Executive Summary

This summary, and the overview that follows, are intended to provide a synopsis of the recent month's observations in addition to longer term variations over the life of the project to date.

September 2023

- The Australian Baseline Sea Level Monitoring Array (ABSLMA) network continued to collect high quality sea level and associated meteorological information to support long-term sea level monitoring around Australia.
- The overall rate of sea level data returned from the operating network during September 2023 was 93.4%.
- Record-high September sea levels were observed at Portland and Cape Ferguson whilst a record-low September sea level was observed at Thursday Island.
- Monthly mean sea levels in September 2023 were higher than the overall September average for many stations, most notably at Cape Ferguson (+14 cm), Rosslyn Bay and Broome (+6 cm).
- Taking account of astronomical tides, monthly sea level anomalies were negative at many locations including Cocos Islands (-16 cm), Darwin (-11 cm), Groote Eylandt (-9 cm), Thursday Island and Thevenard (-6 cm).

Introduction

Welcome to the September 2023 Monthly Data Report for the Australian Baseline Sea Level Monitoring Array (ABSLMA). The report details the month-by-month operation of SEAFRAME sea level monitoring stations around Australia, including operational problems with the network and the occurrence of abnormal sea level events in the context of related astronomical tide, weather, and climate variations. A companion array of SEAFRAME sea level monitoring stations in Pacific Island Countries is supported under the Pacific Sea Level and Geodetic Monitoring Project.

The ABSLMA was originally developed and supported from grants under the Australian Climate Change Science Program through the Department of Climate Change and Energy Efficiency, with a primary goal to monitor long-period sea level changes around Australia focussing particularly on the enhanced greenhouse effect. Operation of the array continues to be supported by the Bureau of Meteorology, underpinning the advanced technologies gathering global observations for climate change research as well as providing real-time information for tidal monitoring and tsunami detection.

The Baseline sea level monitoring array consists of 15 standard SEAFRAME stations operated by the Bureau of Meteorology at representative sites around Australia, as well as two customised,

privately-owned stations at Lorne and Stony Point (Figure 1). The SEAFRAME at Port Stanvac was removed in November 2010 to allow Mobil Refining Australia to decommission the oil refinery. Re-establishment of a tide gauge near Port Stanvac is being investigated.

The standard SEAFRAME stations not only measure sea level, but also observe several “ancillary” variables - air and water temperatures, wind speed, wind direction and barometric pressure. The privately-owned stations at Lorne and Stony Point do not measure the ancillary variables, although winds are measured at Stony Point.

The Bureau of Meteorology and Geosciences Australia, through their membership on the Intergovernmental Committee on Surveying and Mapping (ICSM) Tides and Sea Level Working Group (TSLWG), strive to sustain geodetic levelling programs implemented by various state surveying organisations in order to monitor shifts in the vertical of the sea level sensors due to local land movement.

Observations collected by the sea level monitoring network are routinely processed into a range of quality-controlled data products. The monthly data report is the primary source of up-to-date information relating to these data products.

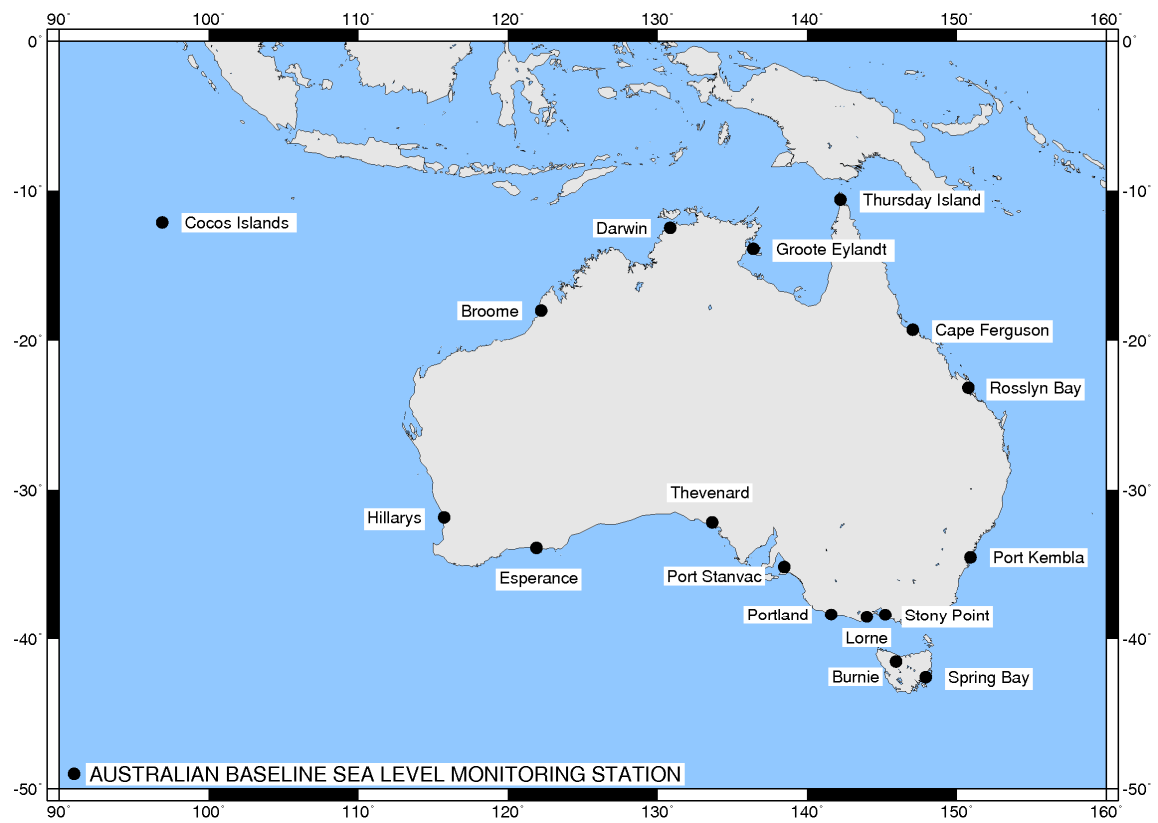

Figure 1. Australian Baseline Sea Level Monitoring Network of SEAFRAME stations.

Sea Level and Climate

Astronomical tides and weather conditions are largely responsible for daily perturbations in sea level, but over monthly, seasonal, and longer timescales sea levels around Australia are largely influenced by fluctuations in climate and ocean heat content.

Intra-annual or seasonal changes in sea level are closely linked to the annual solar radiation cycle and associated shifts in weather patterns and ocean current systems. Across southern Australia, sea levels tend to be at their highest during winter, while the opposite is true across northern Australia, where sea levels tend to be higher during the summer wet season. Further information relating to seasonal climate variations around Australia is provided by the Bureau of Meteorology at <http://www.bom.gov.au/climate/>

Inter-annual sea level variations are largely influenced by the El Niño – Southern Oscillation climate cycle, particularly across the northern and

western Australian coastlines. Sea levels are generally lower than normal around Australia during El Niño, in response to cooler than normal ocean temperatures and higher than normal barometric pressures that are brought about by weaker than normal easterly Trade Winds across the Pacific. Conversely, during La Niña sea levels around Australia are generally higher than normal, in association with warmer than normal ocean temperatures and lower than normal barometric pressures, due to stronger than normal easterly Trade Winds across the Pacific.

A summary of recent and past El Niño – Southern Oscillation climate conditions is provided by the Bureau of Meteorology at <http://www.bom.gov.au/climate/enso/>

September SEAFRAME Data

Monthly Sea Level and Environmental Data

The observed sea levels (Figure 3) are dominated by the daily oscillations of the tide. In most cases, the tide rises and falls twice per day (semi-diurnal), but at Groote Eylandt and Hillarys the tide tends to have a single high and low per day (diurnal). Where the tides follow a semi-diurnal pattern, the greatest tidal variations are called spring tides, which tend to occur around the time of the new and full moons. A new moon fell on the 15th of September, while a full moon fell on the 29th of September.

Gaps in the data are the result of instrumental errors or data retrieval problems and are discussed under Instrument Performance.

The residuals (Figure 4) are the differences between the observed sea levels and the astronomical tidal predictions. They highlight non-tidal sea level fluctuations, such as those due to the effects of weather or tsunamis.

Low pressure systems can produce storm surges where the combination of low barometric pressure and strong winds raise sea levels well above the predicted astronomical tides for a period of a day or more.

The non-tidal sea level fluctuations can be amplified or sustained by the shape of the bay or harbour in which the gauge is located. Some of the SEAFRAME stations are located in harbours that exhibit 'sloshing' under certain conditions (a phenomenon referred to as a seiche).

The sea level residuals at all stations from time to time and to some degree exhibit semi-diurnal or diurnal fluctuations which last a few days or weeks and then disappear. If these fluctuations were to persist, they would form part of the astronomical tide prediction and thus not appear as residuals. Consequently, semi-diurnal and diurnal residual fluctuations will always be transient in nature.

The barometrically corrected residuals (Figure 5) have had a major part of the effect of atmospheric pressure fluctuations removed from the sea level residuals of Figure 4. The rule of thumb for the 'inverse barometer effect' is that a 1-hPa fall in the barometer, if sustained over a day or more, produces a 1-cm rise in the local sea level (within the area beneath the low-pressure system).

The winds, temperatures and barometric pressures are plotted in Figure 6 to Figure 11. The incident winds in Figure 8 follow the meteorological convention, that is, they point in the direction the wind is coming from. For example, the winds at Cocos Island were from the south-east direction for much of September.

Air and water temperatures (Figure 9 and Figure 10) are plotted using the same vertical scale for the purpose of comparison. The air temperatures are seen to fluctuate over a much wider range than the water temperatures.

Barometric pressures (Figure 11) tend to fluctuate by around 3 hPa twice daily at all stations as a

result of atmospheric tides, which are largest in the tropical regions and reduce to near zero toward the poles. The longer-term barometric pressure fluctuations that occur over periods of days to weeks are due to passing weather systems. These fluctuations tend to be larger at sites farther away from the equator, particularly those along the southern Australian coastline.

The monthly data extremes are put into perspective by Figure 12. In this figure, if an open circle falls above (below) a solid dot, a new maximum (minimum) for the particular month has been set. The data sets only include the ABSLMA data, which have been collected since May 1990 when the first station was installed at Darwin.

The SEAFRAME station at Thursday Island has only been collecting data since April 2015, and the monthly data extremes do not include data from an earlier tide gauge. The short data records for Thursday Island means that extreme levels are exceeded on a regular basis.

When the long-term September sea levels were considered, record-high September sea levels were observed at Portland (1.413 m) and Cape Ferguson

(3.650 m), while a record-low sea September sea level of 0.245 m was observed at Thursday Island this month.

Monthly mean sea levels in September 2023 were higher than the long-term September mean for most of the stations (Figure 12), most notably at Cape Ferguson (+14 cm), Rosslyn Bay and Broome (+6 cm), but slightly lower at several sites, most notably at Cocos Island (-4 cm).

Record-high September air temperatures were observed at Thevenard (32.2 °C), Portland (28.3 °C), Burnie (20.3 °C) and Port Kembla (32.1 °C).

Record-high September water temperatures were observed at Broome (28.6 °C) and Thevenard (19.1 °C).

Barometric pressures for all sites fell within the long-term September extremes this month.

Further sea level and meteorological statistical information is available at <http://www.bom.gov.au/oceanography/projects/abslmp/data/monthly.shtml>

Monthly Means and Anomalies

Figure 13 through Figure 16 show the monthly means, or simple arithmetic averages, for sea level, barometric pressure, water temperature and air temperature. The monthly means demonstrate the seasonal variations of the recorded parameters. Groote Eylandt, for example, normally experiences an annual sea level cycle of about 0.6 m that peaks around February of each year.

Figure 17 through Figure 20 show the monthly mean sea level, barometric pressure, air temperature and water temperature anomalies. The sea level anomalies are the residuals after tides, annual and semi-annual seasonal cycles and linear slope have been removed by way of harmonic tidal analysis of the complete record. The annual sea level cycle at Groote Eylandt (which has the largest consistent annual cycle) is quite notable in Figure 13 but less apparent in Figure 17. By removing the seasonal cycles, the anomalies help to bring out irregular features, such as lower than normal sea levels around much of Australia during the 1997/98 El Niño.

The following sea level, barometric pressure, air and water temperature anomalies were observed for September 2023.

Sea level anomalies were negative at most locations this month, most notably at Cocos Islands (-16 cm), Darwin (-11 cm), Groote Eylandt (-9 cm),

Thursday Island and Thevenard (-6 cm), but positive at Cape Ferguson (+4 cm).

Monthly mean barometric pressures were higher than normal at most locations, most notably at Port Kembla (by +4.1 hPa), Rosslyn Bay (+3.0 hPa), Burnie and Spring Bay (+2.6 hPa), Cape Ferguson (+2.5 hPa) and Portland (+2.4 hPa).

Monthly mean water temperatures were warmer than normal at all sites this month, most notably at Broome (by +1.4 °C), Port Kembla (+1.2 °C), Thevenard and Burnie (+1.1 °C) and Spring Bay (+0.8 °C), but cooler than normal at Thursday Island (by -0.6 °C).

Monthly mean air temperatures were warmer than normal at all sites this month, most notably at Thevenard and Esperance (by +1.9 °C), Port Kembla and Portland (+1.6 °C) and Spring Bay (+1.3 °C).

Overall Rate of Movement in Sea Level

Table 1 shows the overall rate of movement in sea level at individual Australian Baseline stations based on the data so far collected at those sites. For most sites, the underlying data sets now exceed twenty years in length, Port Stanvac and Thursday Island being the exception.

The overall rates of movement are updated every month by calculating the linear slope during the tidal analysis of all the data available at individual stations. The rates are relative to the SEAFRAME

sensor benchmark, whose movement relative to inland benchmarks is monitored by Geosciences Australia.

Please exercise caution in interpreting the overall rates of movement of sea level – the records are too short to be inferring long-term trends and have not been corrected for land movement or other parameters that may influence the reported rates.

Table 1. Updated overall rates of sea level movement based on SEAFRAME data from installation through September 2023.

Location	Latitude	Longitude	Date of first data	Rate ¹ (mm/yr)	Change in rate from previous month (mm/yr)

Instrument Performance

In Figure 21, which shows sea level data return, the columns represent the percentage of quality-controlled data returned from the gauge each month.

Sea level data return from the operating network during September 2023 was at a rate of 93.4% (Table2).

The station at Hillarys returned no data in September, having been temporarily removed on 25th July 2023 as part of a planned upgrade of the boat harbour including the station infrastructure, while communication issues at Lorne resulted in the loss of a day's data.

With regards to the ancillary meteorological and oceanographic sensors, the water temperature sensors at Esperance, Portland and Cape Ferguson

remained faulty during September 2023, while the sensor at Cocos Island began to malfunction from the 18th and erroneous data were removed from the record.

The air temperature sensor at Thursday Island remained faulty throughout September 2023.

Intermittent barometric pressure sensor outages occurred at Broome while the barometric pressure sensor at Cocos Island remained faulty throughout September 2023.

Wind data for Stony Point remained suspect for the whole month and has been excluded from the archived record. The anemometers at Esperance and Spring Bay were removed in 2012 and 2014 respectively, due to infrastructure changes at those sites.

Table 2. Rates of sea level data return.

Location	Installation Date	Data Return Since Installation (%)	Data Return in September 2023 (%)
Cocos Islands	Sep 1992	98.4	100
Groote Eylandt	Sep 1993	98.3	100
Darwin	May 1990	99.8	100
Broome	Nov 1991	97.5	100
Hillarys	Nov 1991	99.3	0.0
Esperance	Mar 1992	97.9	100
Thevenard ²	Mar 1992	94.8	98.7
Port Stanvac ¹	Jun 1992	n/a	n/a

SEAFRAME Stations

Standard SEAFRAME stations now employ a TELMET (previously SUTRON) programmable data logger, water level gauges and other sensors. The data logger and associated electronics are normally housed in fibreglass huts. A sketch of a typical SEAFRAME station is shown in Figure 2.

Water level sensors include:

1. Primary water level using a Bartex 'AQUATRAK' acoustic-in-air sensor,
2. Secondary water level (or backup) using a Druck pressure transducer mounted close to the seabed, and
3. Tertiary water level using a Vega-puls62 radar sensor mounted above the water.

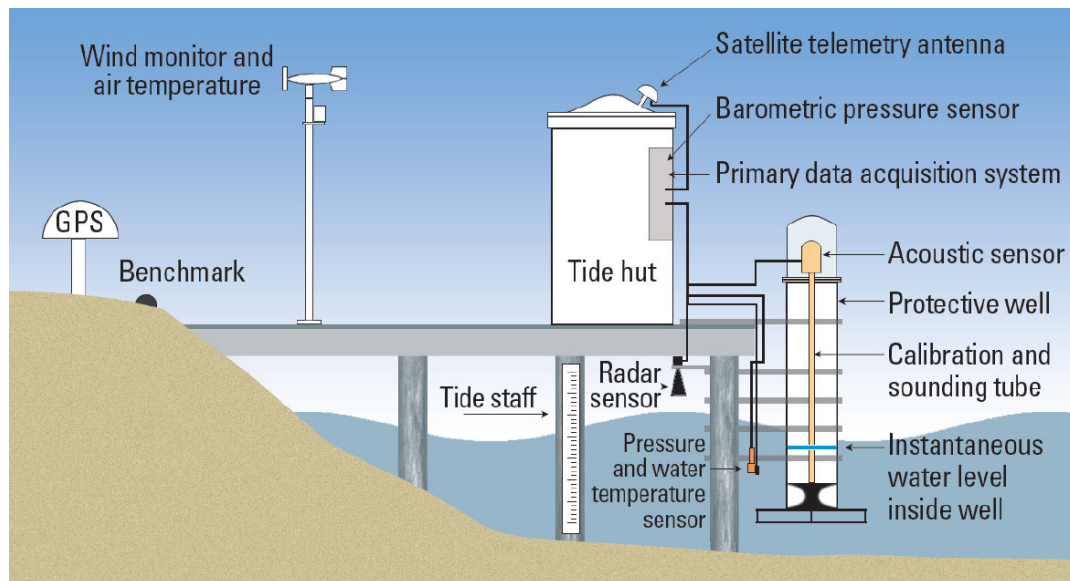

Figure 2. Schematic diagram of a SEAFRAME sea level monitoring station.
